### 1. Timing Analysis

Constant Delay Case

Variable Delay

Switched System

Problem of Switched System

### 2. Stability Analysis

Instability due to Switching

Common Quadratic Lyapunov Functions (CQLF) Analysis

Calculation of CQLF: LMIs

Summary

For workload variation case, we will still use the example IBC system used in last part. But now, we assume we assume the workload of the RolMerging step will vary during execution.

## 1. Timing Analysis

### Constant Delay Case

Simplest, we can just use the worst-case model and set a constant sensor-to-actuator delay, which means, the system will have some **idle time**

### Variable Delay

If we do not use worst-case model, then we will introduce variable delay case.

System closed-loop dynamic keeps switching between different (sampling period and delay) combinations:

$$(h_1, \tau_1) \rightarrow (h_2, \tau_2) \rightarrow (h_3, \tau_3) \rightarrow (h_4, \tau_4) \rightarrow (h_5, \tau_5) \dots$$

### Switched System

Then we will have a switched system with switched state-space model

### Problem of Switched System

A big problem of Switched System is that sometimes we cannot guarantee the stability easily, like shown in the following graph

$$S_1: \begin{bmatrix} 0.7906 & -1.8323 \\ 0.1832 & 0.7906 \end{bmatrix} \rightarrow \text{poles at } 0.98, 0.98 \rightarrow \text{stable}$$

$$S_2: \begin{bmatrix} 0.7906 & 0.1832 \\ -1.8323 & 0.7906 \end{bmatrix} \rightarrow \text{poles at } 0.98, 0.98 \rightarrow \text{stable}$$

- Switched system
  - $(S_1 S_2)^w: S_1 \rightarrow S_2 \rightarrow S_1 \rightarrow S_2 \dots \text{repeats}$
  - $z[k+2] = S_1 S_2 z[k] \rightarrow \text{poles of } S_1 S_2 \rightarrow 4.43, 0.21 \rightarrow \text{unstable}$
- Switched system
  - $(S_1^5 S_2)^w: S_1 \rightarrow S_1 \rightarrow S_1 \rightarrow S_1 \rightarrow S_1 \rightarrow S_2 \dots \text{repeats}$
  - $z[k+6] = S_1 S_1 S_1 S_1 S_1 S_2 z[k] \rightarrow \text{poles of } S_1 S_1 S_1 S_1 S_1 S_2 \rightarrow 0.89, 0.89 \rightarrow \text{stable}$

From the two discussed cases, we can find that the stability of the such system depends on exact order of switching, even though each sub-system is stable

## 2. Stability Analysis

For switched system, we need analyze its stability:

- For switching pattern that is known at the design time
  - Compute System Poles and check for stability directly
- Switching pattern are unknown at the design time
  - We need to use some analysis tools:
    - Common Quadratic Lyapunov Function (CQLF)
    - Switched Lyapunov Function (SLF)
    - Multiple Lyapunov Function (MLF)

### Instability due to Switching

From energy lypunov perspective, the instability due to switching may be illustrated in the following graph

In each sampling period, the energy decrease, but it increase at each sampling point

## Common Quadratic Lyapunov Functions (CQLF) Analysis

### Theorem: Common Quadratic Lyapunov Functions (CQLF)

Assume we have two systems:

- System A:  $x[k+1] = A_1 x[k]$ 
  - Lyapunov Function for System A  $V_A(x[k]) = x^T[k] P_1 x[k]$
- System B:  $x[k+1] = A_2 x[k]$ 
  - Lyapunov Function for System B  $V_B(x[k]) = x^T[k] P_2 x[k]$

If the system has a common  $P$ , i.e.  $P_1 = P_2 = P$ , which means  $V_A(x[k]) = V_B(x[k]) = V(x[k])$ , then

There exists a  $P = P^T > 0$  such that  $V(x[k]) = x^T[k] P x[k]$  is Lyapunov function for both System A and B; this is called **CQLF**.

### Calculation of CQLF: LMIs

The switched system is **stable for any arbitrary switching** between systems  $A_i$  if there exists solution  $P$  for the following Linear Matrix Inequalities (LMIs)

$$\begin{aligned} P &= P^T > 0 \\ P - A_i^T P A_i &> 0 \quad \forall i \end{aligned}$$

## Summary

- If we do not use WCET model, we may have a switched system
  - hard to guarantee stability even if each sub-system is stable
- Stability Analysis of Switched System
  - CQLF Analysis
